I'll build the full Next.js + Payload CMS + PostgreSQL storefront in this workspace. First I'm checking the environment (Node, npm, PostgreSQL, network access), then I'll scaffold the project and work through it phase by phase.

Created 8 files, shared a file, and 234 more steps +11

I've finished the full store: Next.js with a Payload CMS admin panel and PostgreSQL. It's in `mango-shop.zip`, and every test passes against the production build.

What it includes

- **Storefront:** Bangla at `/bn` by default, full English at `/en`.
  - Homepage with every section from your brief, shop with search and filters, category and product pages.
  - Cart and checkout with server-side pricing, cash-on-delivery orders, private order links, and order tracking by order number + phone.
  - The add-to-cart button with all its states, the floating WhatsApp button, and SEO for both languages (canonical/hreflang, sitemap, structured data).
- **Admin at `/admin`:**
  - Dashboard showing real data.
  - Products with pack-size variants and a stock history, categories, orders with printable invoices and CSV export, coupons, homepage and all other content.
  - Branding, WhatsApp, delivery, payments and analytics settings, plus admin/manager/editor roles.
- **Deployment:** Docker files, Nginx, PM2 and systemd configs, a backup script, `.env.example`, and three guides: `README.md`, `docs/DEPLOYMENT.md` (Hostinger-style VPS) and `docs/ADMIN-GUIDE.md`.

Versions: Next.js 16.4.3, Payload 3.92.0, React 19.2, PostgreSQL 16, Node 22.12 or newer.

Tests I ran

- Lint, type check and production build: all pass.
- 46 unit tests: pass (prices, discounts, cart, delivery, coupons, checkout validation, translations, SEO, permissions, rate limiting).
- 19 integration tests on a separate test database: pass. They include six people buying the last unit at once (exactly one order succeeds, stock never goes below zero), a double-clicked checkout (one order), and a cancelled order (stock is restored).
- 26 browser tests on desktop and mobile: pass. They cover everything from homepage, language switching, search and cart through checkout, admin edits, branding, translations, SEO and the WhatsApp button. Phone widths 320–768px show no sideways scrolling.

Bugs I found and fixed while testing

- **English translations weren't being saved.** Every English edit was silently lost, so the English site showed Bangla. Fixed, and covered by tests.
- **The language choice could flip on its own.** Background page preloading overwrote it. Fixed.
- **Security gaps closed:**
  - Anyone reaching `/admin` first on a new server could have made themselves admin.
  - The seed data set a made-up WhatsApp number that could belong to a real person.
  - The rate limiter could be bypassed with a fake header.
  - Uploaded SVG images could carry scripts.
  - A critical Next.js advisory needed a version update.

Limitations

- **I couldn't test the Docker build here** because Docker Hub is blocked from this workspace. I did run the same production files the image uses: it set up an empty database on start and served the site and admin.
- **bKash, Nagad and SSLCommerz are untested.** They're built to each provider's documented flow and only mark an order paid after confirming with the provider and matching the amount. Each needs testing with your sandbox credentials before going live.
- **There are no customer accounts.** Customers check out as guests and track orders by number + phone.
- **Product images are illustrations I generated,** not photos, and all prices, stock and policy wording are samples. Swap in your own product renders or photos before launch.
- **"আমকুঞ্জ / Amrokunjo" is a placeholder brand name.** Change it in the admin.

What you need to do

1. Get a VPS and a domain, and point the domain's DNS at the server.
2. Follow `docs/DEPLOYMENT.md`. Set `NEXT_PUBLIC_SERVER_URL` to your exact public `https://` address, or admin saves will be refused.
3. Run `npm run create-admin` on the server to make your login. There is no default password.
4. Add your WhatsApp number in the admin; the button stays hidden until you do.
5. Optional: SMTP details for order emails, payment gateway sandbox credentials, and S3 storage if you want media off the server.

Mango shop
ZIP

Progress

payments
Bilingual storefront: layout, homepage, shop, product, cart, checkout, tracking, blog, pages
SEO: metadata, hreflang, sitemaps, robots, JSON-LD, redirects, analytics
Admin dashboard extras: stats view, invoice, CSV export, translation status
Seeding sample data
Tests: unit/integration (Vitest) and E2E (Playwright)
Deployment: Docker, Compose, PM2, Nginx, docs, README
Verify: visual check at breakpoints, project tree audit, package & deliver
Get existing code type-checking and linting cleanly
Finish seed data and run it
Production build and visual QA of storefront
Write unit, integration and Playwright e2e tests and run them
Docs, Docker, env example, deployment guide
Final verification and package delivery

Outputs

Mango shop ZIP

Okay, great, where is the frontend? Which directory and how can I make some tiny adjustments like logo size or HTML, CSS, or JavaScript?

Read logo component and design tokens ▸

The frontend is in `src/` inside the project. It isn't plain `.html` / `.css` / `.js` files, though. Each part of the page is a React component (a `.tsx` file), and the HTML, the styling and any JavaScript for that part live together in the same file. Styling is done mostly with Tailwind classes written right on the HTML tags (`class="h-10 w-auto"`), plus one global stylesheet.

Where things are

You want to change…	Edit this file
Logo size	`src/components/layout/Logo.tsx`
Header (menu, search icon, header height)	`src/components/layout/Header.tsx`
Footer	`src/components/layout/Footer.tsx`
Announcement bar	`src/components/layout/AnnouncementBar.tsx`
Homepage hero	`src/components/home/Hero.tsx`
Other homepage sections (categories, promo, story, FAQ…)	`src/components/home/sections.tsx`
Product cards	`src/components/product/ProductCard.tsx`
Add to cart button	`src/components/product/AddToCartButton.tsx`
Cart drawer / cart page	`src/components/cart/CartDrawer.tsx` , `CartView.tsx`
Checkout form	`src/components/checkout/CheckoutForm.tsx`
WhatsApp button	`src/components/whatsapp/WhatsAppButton.tsx`
Colours, fonts, corner roundness, global CSS	`src/app/(frontend)/globals.css`
Page layouts (homepage, product page, shop…)	`src/app/(frontend)/[lang]/…/page.tsx`
Button labels and other interface text	`src/lib/i18n/dictionaries/bn.ts` and `en.ts`

Products, prices, homepage wording, the logo image itself, colours and the WhatsApp number are all changed in the admin panel, not in code.

Example: making the logo bigger

In `src/components/layout/Logo.tsx` , the size is set by these Tailwind classes:

```tsx
className={`h-10 w-auto ...`}            // uploaded logo on phones: 40px tall
className="hidden h-11 w-auto md:block"  // uploaded logo on desktop: 44px tall
```

Change `h-10` to `h-12` (48px) or `h-14` (56px). Tailwind's `h-` units are multiples of 4px, and `w-auto` keeps the proportions. You can also use an exact size, like `h-[52px]` .

If you haven't uploaded a logo yet, the site shows the built-in mango icon and the brand name. Those are controlled by `h-9 w-9` (the icon) and `text-[1.45rem]` (the name text) further down the same file.

If the logo gets taller than about 56px, raise the header height too. In `Header.tsx` , find `h-16 md:h-[72px]` (64px on phones, 72px on desktop) and increase it.

Plain CSS

If you'd rather write normal CSS, add it at the bottom of `src/app/(frontend)/globals.css` :

```css
header img { height: 52px; }
```

Brand colours and the card/button corner rounding are near the top of that file (`--radius-card: 14px;` and so on). Tailwind classes in the components usually win over plain CSS, so if a rule doesn't seem to apply, change the class in the component instead.

How to see changes

On your computer:

```bash
npm run dev
```

Open `http://localhost:3000` , edit a file and save, and the browser updates instantly. Nothing needs restarting.

On the live server, changes only appear after a rebuild:

```bash
npm run build
pm2 restart mango-shop
```

Before rebuilding the live site, run `npm run typecheck`; it catches most typos in a few seconds. If you tell me what you'd like to adjust (for example, "logo 20% bigger and the hero headline smaller"), I can make the edits and send you the updated files.
